

Coagulation abnormalities in COVID-19 patients

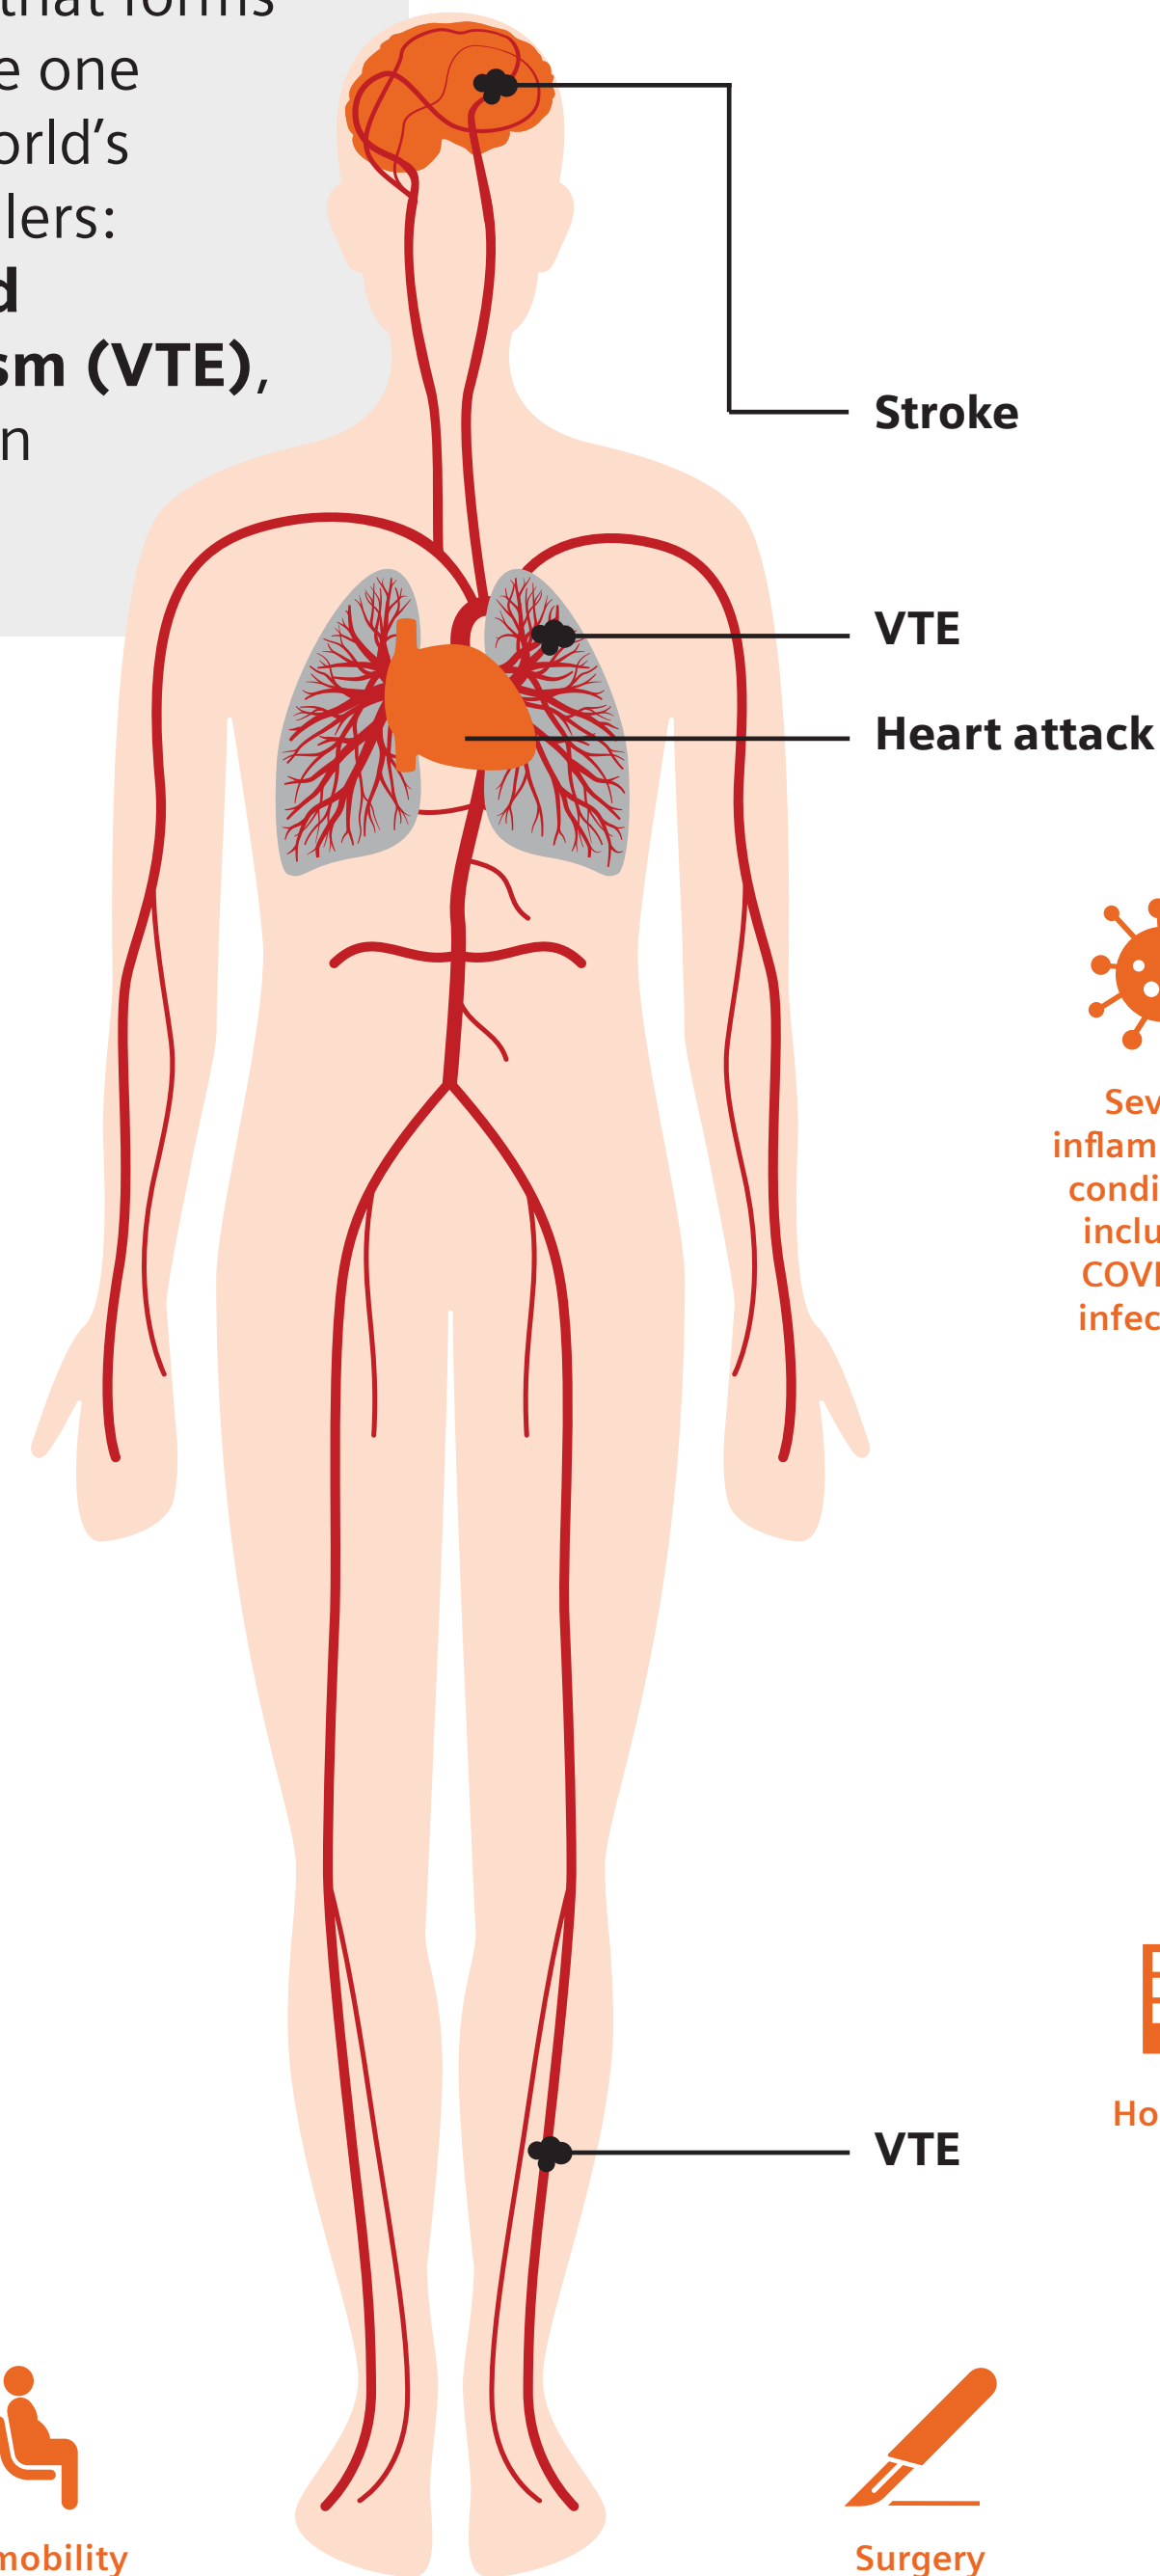

Supporting labs in the diagnosis, treatment, and management of COVID-19 patients

COVID-19 patients are experiencing serious—and sometimes fatal—clotting abnormalities.

Studies show that **about 25%¹—or even up to 70%²**—of critically ill patients have confirmed venous thromboembolism (VTE) or pulmonary embolism (PE).

What is thrombosis?

Thrombosis is a blood clot that forms in an artery or vein. It is the one disorder that causes the world's top three cardiovascular killers: **heart attack, stroke, and venous thromboembolism (VTE)**, a blood clot found mostly in the leg and lungs.

Risk Factors

Cardiovascular disease

Diabetes

Estrogen-based therapy

Pregnancy

Immobility

Surgery

Severe inflammatory conditions, including COVID-19 infections

Family history

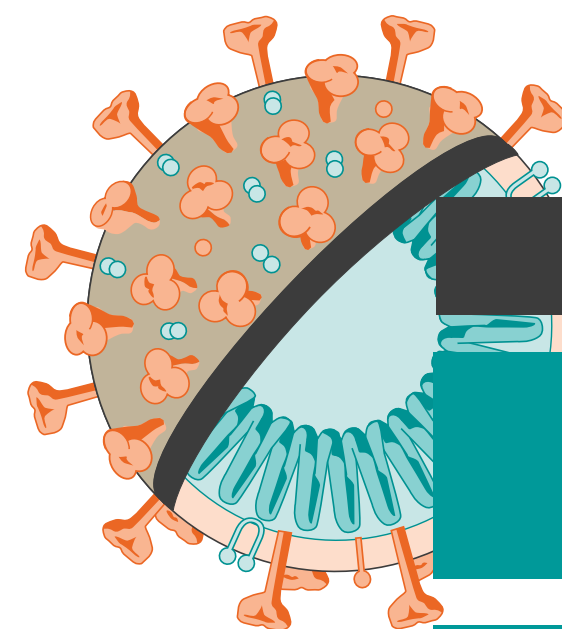

Hospital stay

In one study,

~70%

of COVID-19 patients who died had **disseminated intravascular coagulation (DIC)**.³

Disseminated intravascular coagulation is a condition in which small blood clots develop throughout the bloodstream, blocking small blood vessels. The increased clotting depletes the platelets and clotting factors needed to control bleeding, causing excessive bleeding.

Hospitalized Patients	
Early to mid-term phase	Critical phase
↑ D-dimer	↓ Platelet count
↑ PT INR	↓ Antithrombin
↑ Fibrinogen*	↓ Fibrinogen*

Siemens Healthineers has been recognized as a global leader in hemostasis testing for more than

40 years.

A study showed COVID-19 patients with **D-dimer levels >2 mg/L FEU were 50 times more likely to die than patients with D-dimer levels <2 mg/L FEU.**⁶

Elevated D-dimer levels were found to be a crucial laboratory marker to indicate a thrombotic risk in COVID-19 patients.³⁻⁵ Following a COVID-19 diagnosis, hemostasis testing, therapy, and monitoring have been shown to play a decisive role in COVID-19 patient management.

Increased production of vital coagulation assays

Our coagulation tests are playing an important role in the diagnosis, treatment, and management of coagulation abnormalities in COVID-19 patients. Due to increased demand of these tests, Siemens Healthineers has increased production volumes to respond to the pandemic.

*Fibrinogen levels are increased in hospitalized patients due to inflammation in the early to mid-term phase of COVID-19.⁷ If patients progress to a critical phase of COVID-19, fibrinogen levels are markedly reduced, as observed in DIC.²
